Despite increasing communication, accelerating policy and management responses, and notwithstanding improving ecosystem assessment and endangered species knowledge, conserving biodiversity continues to be more a concern than an accomplished task. Why is it so?The overexploitation of natural resources by our species is a frequently recognised factor, while the short-term economic interests of governments and stakeholders typically clash with the burdens that implementing

This book develops a different perspective on the problem by exploring the conceptual challenges and practical defiance posed by conserving biodiversity, namely: on the one hand, the difficulties in defining what biodiversity is and characterizing that “thing” to which the word ‘biodiversity’ refers to; on the other hand, the reasons why assessing biodiversity and putting in place effective conservation actions is arduous.

This book comprehensively describes essential research and projects on climate change and biodiversity. Moreover, it includes contributions on how to promote the climate agenda and biodiversity conservation at the local level. Climate change as a whole and global warming in particular are known to have a negative impact on biodiversity in three main ways. Firstly, increases in temperatures are detrimental to a number of organisms, especially those in sensitive habitats such as coral reefs and rainforests. Secondly, the pressures

posed by a changing climate may lead to sets of responses in areas as varied as phenology, range and physiology of living organisms, often leading to changes in their lifecycles (especially but not only in reproduction), losses in productivity or even death. In some cases, the very survival of very sensitive species may be endangered. Thirdly, the impacts of climate change on biodiversity will be felt in the short term with regard to some species and ecosystems, but also in the medium and long term in many biomes. Indeed, if left unchecked, some of these impacts may be irreversible. Many individual governments, financial institutes and international donors are currently spending billions of dollars on projects addressing climate change and biodiversity, but with little coordination. Quite often, the emphasis is on adaptation efforts, with little emphasis on the connections between physio-ecological changes and the lifecycles and metabolisms of fauna

and flora, or the influence of poor governance on biodiversity. As such, there is a recognized need to not only better understand the impacts of climate change on biodiversity, but to also identify, test and implement measures aimed at managing the many risks that climate change poses to fauna, flora and micro-organisms. In particular, the question of how to restore and protect ecosystems from the impact of climate change also has to be urgently addressed. This book was written to address this need. The respective papers explore matters related to the use of an ecosystem-based approach to increase local adaptation capacity, consider the significance of a protected areas network in preserving biodiversity in a changing northern European climate, and assess the impacts of climate change on specific species, including wild terrestrial animals. The book also presents a variety of case studies such as the Yellowstone to Yukon Conservation Initiative,

Rather than being mired down with facts and vocabulary, the typical non-science major student needs information presented in a way that is easy to read and understand. Even more importantly, the content should be meaningful. Students do much better when they understand why biology is relevant to their everyday lives. For these reasons, Concepts of Biology is grounded on an evolutionary basis and includes exciting features that highlight careers in the biological sciences and everyday applications of the concepts at hand. We also strive to show the interconnectedness of topics within this extremely broad discipline. In order to meet the needs of today's instructors and students, we maintain the overall organization and coverage found in most syllabi for this course. A

From global-scale variation in the distribution of light reaching the Earth's surface to the smallest chemical gradients, environmental heterogeneity, or variation in environmental conditions over space and time, is critical to explain process and pattern in nature. Environmental heterogeneity has long been hypothesized to promote

species coexistence by allowing niche partitioning. Organisms respond to heterogeneity in abiotic environmental conditions at several scales, interactions between organisms can be mediated by heterogeneity, and organisms themselves can generate additional heterogeneity that may be important for the structure of communities. Importantly, how environmental heterogeneity interacts with biodiversity remains an important challenge to predicting the ecosystem functioning. Moreover, given that environmental conditions and ecological process change across scales of space and time, investigating how heterogeneity influences ecological communities – both directly by

modifying habitat quality and indirectly by modifying interactions – across a range of scales is necessary if we want to make predictions in community ecology. Ecologists often observe and measure communities at a single scale, which often not the scale at which processes take place, so defining appropriate scales for inquiry can be challenging. If a single scale is chosen, ecologists must consider the natural history of their systems that relate to the patterns and processes being investigated. However, the ability of ecologists to view systems at several scales at once is improving with technological advances. My goal with this dissertation was to take what we already know about biodiversity

maintenance and ecosystem functioning and extend it to multiple trophic levels, habitats, and scales of observation, all of which are important to our general understanding of community ecology. The real world is messy, which makes the job of a community ecologist simultaneously fascinating and frustrating. However, by considering some of the complexities inherent in natural systems (including how they might change across scale) I aim to help in pushing biodiversity science into the 21st Century. All of the following chapters explore some aspect of environmental heterogeneity and how it either influences biodiversity or interacts with it to determine some important ecological process. Chapter 1 explores

temporal variation in a major environmental gradient in marine habitats, water flow, and how it interacts with species diversity of suspension feeding invertebrates to predict community-wide water filtration. I manipulated species diversity of suspension feeders and the presence of water flow directly in the lab and allowed communities to consume a diverse mélange of phytoplankton. By tracking chlorophyll a concentrations over time, I was able to get a proxy for water filtration taking place at the community-level. Species diversity enhanced community filtration, and this response did not depend on whether water was flowing or not. However, individual species and pairs did respond to flow, so these

results suggest that interactions between organisms and their modification of water flow may be important for predicting food delivery and ultimately water filtration over time. The balance of competition and niche complementarity appeared to change across flow regimes, which brings species interactions, and their sensitivity to environmental conditions, to the forefront. Chapter 2 investigates a common form of spatial heterogeneity on a rocky shore, namely topography generated by space-holding barnacles and how it interacts with grazer species diversity to drive algal community succession. This chapter was part of a project started by Kristin Aquilino in which we

simultaneously manipulated barnacle cover and snail grazer diversity at small scales relevant to seaweed-grazer interactions. Then we tracked communities over time as they recovered from algal clearing. The presence and heterogeneity of barnacles along with the diversity and identity of grazing invertebrates interacted to predict algal succession. Grazer diversity itself was important for suppressing early successional microalgae, while later successional macroalgae were promoted by the presence of a key limpet grazer. In the absence of this limpet heterogeneity in barnacle cover led to increased algal accumulation. Again, species interactions and the potential for niche complementarity depended on habitat

heterogeneity, thus the influence of environment on interactions remains strong thread in the dissertation. Chapter 3 also considers topographic heterogeneity on rocky shores, but this time focusing on how topography at different spatial scales modifies community structure during early succession. We have known for a long time that large elevation gradients on rocky shores are critical for the distributions of organisms, but perhaps small scale environmental variation also matters for these communities as suggested by many previous studies. I decided to manipulate small-scale (mm) topography by making settlement plates that mimicked real rock surfaces. Then I placed these plates across areas of mid-

intertidal a rocky shore, which represented larger scale (cm to m) variation in topography, including differences in elevation and distance to shore. Importantly, both scales of environmental heterogeneity influenced community composition, but in different ways. Early successional algae responded more strongly to the large-scale heterogeneity present along and across the coastline, while mobile invertebrates responded strongly to small-scale characteristics like rugosity and convexity. It is likely then that small-scale heterogeneity can have a driving influence on algal distributions indirectly through the grazing behaviors of invertebrate animals, but once again this will depend on the traits of the grazers (e.g.,

body size) and how they interact with heterogeneity. One conceptual result that helps tie all of these chapters together is that in order for environmental heterogeneity to be important to ecological communities, the scale at which heterogeneity occurs must match response and effect traits of the organisms living within the community. Body size and the way organisms of a particular size respond to, and potentially modify, their abiotic surroundings play a role in every chapter, from the fouling invertebrates that emerge from the substrate into flowing water (Chapter 1) to the tidepool invertebrates that crawl on bumpy substrates in search of food and refuge (Chapters 2, 3). All of this work, I hope, will help

advance ecological knowledge and our collective ability to make predictions in a changing world. Yet, it is likely that the work presented here will generate more questions than answers. For instance, how do we take the ideas laid out in this dissertation and marry them with life histories, which often cause organisms to experience very different scales of environmental heterogeneity over their lifetimes? If we want to make large-scale predictions about the abundance and distribution of life on Earth and how it responds to environmental change, how much information do we actually need to know at the small scales? Give that body size is important for metabolic rates and impacts on ecosystems, might there

be ways to combine scaling and metabolic theories in ecology, which strive for simplicity, with the messier information about environmental heterogeneity and species traits to make predictions across different types of ecosystems? These are the types of questions that continue to motivate me and that, hopefully, motivates the field of ecology in the future.

health and well-being, foster resilience of urban communities and protect the environment and thereby change urban planning paradigms. Several case studies of emerging transformative planning interventions illustrate practical ways forward. Transformative Planning offers provocative insights into the global planning community's struggle and contribution to tackle the major challenges to society in the 21st century. It will be of use for advanced undergraduate and graduate courses in the wide-ranging fields encompassed by urban studies, sustainability studies, and urban and regional

The Life of a Pest tracks the work practices of scientists in Mexico as they study flora and fauna at scales ranging from microscopic to ecosystemic. Amid concerns about climate change, infectious disease outbreaks, and biotechnology, scientific research in Mexico has expanded its focus to go beyond threats to human life to include threats to animal, plant, and microbial worlds. Emily Wanderer outlines how concerns about biosecurity are leading scientists to identify populations and life-forms as worth saving or as "pests" in need of elimination. Moving from high security labs where scientists study infectious diseases, to offices where ecologists regulate the use of genetically modified organisms, to remote islands where conservationists eradicate invasive species, Wanderer explores how biopolitical research informs, and is informed by, concepts of nation.

This high school classroom supplement to the main biology text prepares students in New York State to succeed on the Regents Exam. It presents a subject review, practice questions with answers, and two complete Regents Biology Exam with answer keys. When combined with Barron's Regents Exams and Answers, Biology, it provides students with the most comprehensive test preparation available anywhere. Topics reviewed include ecology, biological organization, formation and structure of the ecosystem, and the interaction between human beings and the biosphere. This book fills an important gap in the literature, and presents contributions from scientists and researchers working in the field of sustainable development who have engaged in dynamic approaches to implementing sustainability in higher education. It is widely known that universities are key players in terms of the

implementation and further development of sustainability, with some having the potential of acting as “living labs” in this rapidly growing field. Yet there are virtually no publications that explore the living labs concept as it relates to sustainability, and in an integrated manner. The aims of this book, which is an outcome of the “4th World Symposium on Sustainable Development at Universities” (WSSD-U-2018), held in Malaysia in 2018, are as follows: i. to document the experiences of universities from all around the world in curriculum innovation, research, activities and practical projects as they relate to sustainable development at the university level; ii. to disseminate information, ideas and experiences acquired in the execution of projects, including successful initiatives and good practice; iii. to introduce and discuss methodological approaches and projects that seek to

integrate the topic of sustainable development in the curricula of universities; and iv. to promote the scalability of existing and future models from universities as living labs for sustainable development. The papers are innovative, cross-cutting and many reflect practice-based experiences, some of which may be replicable elsewhere. Also, this book, prepared by the Inter-University Sustainable Development Research Programme (IUSDRP) and the World Sustainable Development Research and Transfer Centre (WSDRTC), reinforces the role played by universities as living labs for sustainable development.
