

Spectrophotometric Determination Of Uranium With Arsenazo

An ultraviolet spectrophotometric method for the determination of uranium has been developed which is based on the ultraviolet absorption of the complex of uranium(VI) with tris-(2-ethylhexyl)phosphine oxide. The complex is formed by extracting uranium(VI) from an aqueous 6M sodium nitrate solution in the pH range 2.5-3.0 into 0.1M solution of tris-(2-ethylhexyl)phosphine oxide (TEHPO) in an inert diluent, cyclohexane.

PADAP is a very sensitive reagent for the determination of uranium. The PADAP method is relatively unaffected by the presence of associated ions, particularly if a compensating blank is applied. Only Cr(3+), As(5+), PO₄(3-), and V(5+) have been found to give any serious interference, and the levels of these ions in Witwatersrand ores are usually well below those likely to cause interference. The presence of aluminium extracted from the ores will increase the level at which As(5+) and PO₄(3-) interfere. A comparison of the PADAP method with the thiocyanate method shows that the former has advantages in sensitivity, tolerance for interfering ions, and, possibly, precision. If the PADAP procedure is combined with an extraction step, the tolerance of the method for interferences is increased to an extent where the ions introduced by complete dissolution of a 2 g sample of a silicate ore do not interfere. By the use of this technique it has been shown that the insoluble uranium in Witwatersrand silicate ores varies from 4 to 10 ppm of U₃O₈.

The LASL automated spectrophotometer, designed for determination of 1 to 14 mg of uranium and 0.5 to 14 mg of plutonium, has been evaluated for determination of lower levels of uranium to 0.12 mg. The essentially linear response of absorbance is maintained and the standard deviation for a single measurement is constant at about 0.013 mg of uranium, corresponding to a maximum uncertainty of about 10 percent at the 0.12-mg limit. The instrument was applied to the analysis of a series of low-level-concentration, 0.07- to 0.8-mg/ml uranium samples. The results were not statistically different from those obtained by a manual spectrophotometric method.

The thiocyanate-TBP method has been used daily at the National Institute for Metallurgy for approximately nine years for the determination of small amounts of uranium in Witwatersrand conglomerate and other siliceous ores. It replaced a spectrophotometric method that required the separation of uranium from most other elements in the sample by extraction with ether. The method involves the formation of uranyl thiocyanate complex of uranium in the presence of EDTA and sodium formate, the extraction of the complex into tri-n-butyl phosphate (TBP), and the measurement of the transmittance of the solvent phase. The procedure is applicable to ore samples, filter cakes and aqueous solutions of low uranium content. The thiocyanate-TBP method has several advantages over the 'ether' method.

Evaluation of the LASL Automated Spectrophotometer for Uranium Determination at Submilligram Levels

A spectrophotometric method for determining uranium in nuclear waste was developed using 2-(5-bromo-2-pyridylazo)-5-diethylaminophenol (bromo-PADAP). By extracting the color into Aliquat-336 it was possible to accurately measure U at the 1 .mu.g level. No significant interferences were observed from 34 interfering ions when a tri-n-octylphosphine oxide (TOPO) pre-extraction of U was used. The effect of pH, color development time, bromo-PADAP concentration, and Aliquat-336 concentration were determined. The method was applied to the analysis of alkaline solutions, filtered solids, sludges, and salt cake nuclear waste forms. The standard deviation for the method with a TOPO pre-extraction was +-3.7 percent.

A method for the direct determination of uranium in a cyclohexane solution of tri-n-octylphosphine oxide (TOPO) is presented. The adduct, $UO_2Cl_2 \cdot 2TOPO$, that is formed when uranium(VI) is extracted from hydrochloric acid solutions by tri-n-octylphosphine oxide absorbs light in the ultraviolet region. This absorbance is measured at 230 m μ vs. a TOPO-cyclohexane solution that was contacted with hydrochloric acid of the same concentration as that in the test aliquot. The molar absorbance index is 5500. The method is not selective; of the elements that are extracted by TOPO from hydrochloric acid, iron(III), zirconium, molybdenum, tin and thorium, only thorium can be tolerated. (auth).
