Mechanical ventilation or artificial ventilation refers to the mechanical means that are used in assisting or replacing spontaneous breathing. It is generally carried out by a machine called ventilator or by a qualified anesthesiologist and respiratory therapist. The four types of mechanical ventilators are transport ventilators, intensive-care ventilators, neonatal ventilators and positive airway pressure ventilators. Mechanical ventilation can be classified into invasive and non-invasive ventilation. Invasive ventilation involves the use of an instrument inside the trachea through mouth. Non-invasive ventilation includes usage of masks and is done in conscious patients. The two main types of mechanical ventilation include positive pressure ventilation and negative pressure ventilation. In positive pressure ventilation, air is pushed into lungs through airways whereas negative pressure ventilation involves sucking of air into lungs by stimulating movement of the chest. Mechanical ventilation is used in cases of acute severe asthma, acute lung injury, apnea, hypoxemia, etc. The topics covered in this extensive book deal with the core subject of mechanical ventilation. It provides significant information of this discipline to help develop a good understanding of various types that fall under mechanical ventilation. This book will serve as a reference to a broad spectrum of readers.

If you're looking to improve your ventilator management skills, then you have found the right book. I developed this text as a compendium to my ventilator management textbook, or any of my fellow educators' ventilator management textbooks. The goal was to develop a practice text to help you perfect this truest lifesaving skill. Current research strongly suggests intubated patients in transport fare better when mechanical ventilation is applied.

Mechanical Ventilation Amid the COVID-19 Pandemic

Part 3 : Particular Requirements for Emergency and Transport Ventilators

Lung Ventilators. Particular Requirements for Emergency and Transport Ventilators

This book sets down the fundamentals of the theory and measurement of building ventilation and describes the various techniques for predicting and measuring ventilation. It addresses both envelope flows and internal air motion. The first part of the book is primarily concerned with physical descriptions and theoretical models: starting with an overview of the basic mechanisms and characteristics of envelope flows, it then addresses the treatment of the flow characteristics of individual openings and mathematical models for complete building envelopes. Theories for internal air motion are then discussed in detail: mechanisms of mass transport in terms of air motion and age distribution, primary air flows in isolation, resulting flows in enclosed spaces, and flows through large internal openings. The second part, concerned with measurement techniques both at full scale and at model scale, begins with techniques for determining flow characteristics of envelope openings. The use of tracer gases in the study of age distribution and ventilation efficiency is dealt with in detail. Scale modelling for investigating both envelope flows and internal motions is also addressed. The final chapter deals with Computational Fluid Dynamics, since one of its main applications is an alternative to conventional experimental techniques. Natural ventilation is re-emerging as an alternative to mechanical systems in some commercial buildings and both natural and mechanical ventilation are dealt with in detail.

"The Mobile Intensive Care Unit (MICU) is a combination of i) a team of critical care nurse, physician and ambulance driver, ii) a MICU-trolley (i.e. equipped with cardiovascular monitor, mechanical ventilator, syringe pumps etc. indispensable for safe transport and iii) an Intensive Care ambulance. This thesis describes research on technical and clinical aspects of interhospital critical care transport executed by the MICU of the Academic Medical Centre in Amsterdam. Are new mobile phones and wireless auto-identification techniques (Radio Frequency Identification, RFID) really safe in the critical care environment? When do Dutch intensivists consider critical ill patients suitable for transport and under which conditions? Which new generation transport ventilators are accurate enough to replace an ICU-ventilator during ground critical care transport? Could a critical care nurse assisted by a paramedic safely escort such a transport or is presence of a critical care physician

imperative? Finally, a failure mode effect analysis was performed on the process of interhospital critical care transport with subsequent recommendations."--Samenvatting auteur.

The surge in COVID-19 cases leading to hospitalizations around the world quickly depleted hospital resources and reserves, forcing physicians to make extremely difficult life-or-death decisions on ventilator allocation between patients. Leaders in academia and industry have developed numerous ventilator support systems using both consumer- and industry-grade hardware to sustain life and to provide intermediate respiratory relief for hospitalized patients. This book is the first of its kind to discuss the respiratory pathophysiology underlying COVID-19, explain ventilator mechanics, provide and evaluate a repository of innovative ventilator support devices conceived amid the pandemic, and explain both hardware and software components necessary to develop an inexpensive ventilator support device. This book serves both as a historical record of the collaborative and innovative response to the anticipated ventilator shortage during the COVID-19 pandemic and as a guide for physicians, engineers, and DIY'ers interested in developing inexpensive transitory ventilator support devices. Provides a qualitative appraisal of numerous transitory ventilator devices developed and/or used during the COVID-19 pandemic including non-invasive ventilation; Explores the mechanics, considerations, and concerns of emergency ventilator components; Provides a detailed framework for beginners and experts alike to develop their own emergency ventilation systems.

The VART, or Ventilation and Resuscitation Training, is designed to be intuitively conceptual. We want you to be able to use the VART acronym tool to approach and maintain your patients on mechanical ventilation. However, we do not just want to help you understand HOW to set them up, but we also want to help you think through common and uncommon mechanical ventilation issues. Moreover, we want your ventilator set up to mitigate any alarms that can be set off erroneously. We hope you'll see as you progress through the book and training the mechanical ventilator is an enigma that is absolutely tamable. VART will act as a template for which to begin approaching mechanical ventilation patients. It will be useful for what we call type 1 and type 2 ventilator problems. Type 1 mechanical ventilation problems are those that require a 'from scratch' approach. In these types of ventilator problems, the clinician must ensure adequate perfusion, calculate initial ventilator settings, confirm these initial settings are therapeutically reaching the patient, and then make safe adjustments based on SpO2 and EtCO2. Type 2 is much simpler. In type 2 ventilator problems, the ventilator is already initiated and the clinician's job is to ensure the patient is receiving appropriate and therapeutic mechanical ventilation. If not, they must make safe corrections and then reassess. THE VART ACRONYM While VART stands for the name, Ventilation and Resuscitation Training, the primary VART acronym tool used to assess and manage patients represents four areas of management: Verify, Assess, Revise, and Trend. For each of these 4 areas of management there are secondary VART Acronyms, or subdomains to be used to guide ventilator and patient management. The secondary VART acronym subdomains will be explained in their respective sections.
